Integrated Pest Management Handbook

Smarter, safer and more sustainable crop protection

What is IPM?

Integrated Pest Management (IPM) combines cultural, mechanical, biological and chemical methods to keep pests below damaging levels with the least risk to people, crops and the environment.

The IPM steps

- Prevent: Use healthy seed, resistant varieties, crop rotation, timely sowing and field sanitation.
- Monitor: Scout fields weekly. Use pheromone traps, yellow and blue sticky traps and light traps.
- Decide: Act only when pests reach the Economic Threshold Level (ETL) for your crop.
- Control: Start with biological and mechanical options; use chemicals when needed, at the labelled dose.
- Evaluate: Record results and adjust the plan next season.

Control tools

Method	Examples
Cultural	Crop rotation, intercropping, trap crops, balanced fertilization, clean cultivation
Mechanical	Hand-picking egg masses, pheromone and sticky traps, removing infected plants
Biological	Trichoderma, Pseudomonas, Beauveria, NPV, conserving natural enemies
Chemical	Selective, label-approved pesticides applied at threshold with correct dose

Resistance management

- Rotate products with different modes of action between sprays.
- Never use lower or higher doses than the label recommends.
- Avoid repeated calendar sprays of the same product.
- Combine chemical control with non-chemical methods.
